**SOIL TEST SHOWS WHERE SPUDS SCAB**

So-called Acid Fields Have Least Infection—Russet Rural Best Variety for Limestone Areas.

A survey of 313 New York State potato fields in 1931 and 1932 showed that scab affected 20 per cent. of the tubers from fields of limestone soils; tubers grown in non-limestone soils had nine per cent. infected.

Potatoes are grown extensively on limestone soils in western New York, where no limestone need be applied to grow alfalfa. The district includes: most of Genesee county, southern Monroe and northern Livingston, Ontario and parts of Seneca, Cayuga, Onondaga, and Oneida counties. The counties in the southern tier that grow potatoes have mostly acid, non-limestone soils where scab occurs only in rare spots.

In the districts where scab is most prevalent, the thick skinned varieties like the Russet Rural had the least scab, followed in order by Smooth Rural, Cobbler, and Green Mountain. Up-to-dates had the most scab. Seed treatment apparently reduced the amount of scab from five to 15 per cent. The crop usually had less scab, on the average, when potatoes were planted immediately following sod rather than following cultivated crops. Stable manure, despite the old belief that fresh manure induced scab, made practically no difference in the amount of scabby potatoes.

These findings are reported by F. M. Blodgett of the New York State college of agriculture.
